Dataset Integrity Check for
the Chronic Renal Insufficiency Cohort
(CRIC)

Prepared by Sabrina Chen
3901 Calverton Blvd, Suite 200 Calverton MD 20705
October 12, 2020
1 Standard Disclaimer

The intent of this DSIC is to provide confidence that the data distributed by the NIDDK repository is a true copy of the study data. Our intent is not to assess the integrity of the statistical analyses reported by study investigators. As with all statistical analyses of complex datasets, complete replication of a set of statistical results should not be expected in secondary analysis. This occurs for a number of reasons including differences in the handling of missing data, restrictions on cases included in samples for a particular analysis, software coding used to define complex variables, etc. Experience suggests that most discrepancies can ordinarily be resolved by consultation with the study data coordinating center (DCC), however this process is labor-intensive for both DCC and Repository staff. It is thus not our policy to resolve every discrepancy that is observed in an integrity check. Specifically, we do not attempt to resolve minor or inconsequential discrepancies with published results or discrepancies that involve complex analyses, unless NIDDK Repository staff suspect that the observed discrepancy suggests that the dataset may have been corrupted in storage, transmission, or processing by repository staff. We do, however, document in footnotes to the integrity check those instances in which our secondary analyses produced results that were not fully consistent with those reported in the target publication.

2 Study Background

The Chronic Renal Insufficiency Cohort (CRIC) Study is an observational study that examined risk factors for progression of chronic renal insufficiency (CRI) and cardiovascular disease (CVD) among CRI patients. The study enrolled adults aged 21 to 74 years with a broad spectrum of renal disease severity, half of whom were diagnosed with diabetes mellitus. Subjects underwent extensive clinical evaluation at baseline and at annual clinic visits and via telephone at 6 month intervals. Data on quality of life, dietary assessment, physical activity, health behaviors, depression, cognitive function, health care resource utilization, as well as blood and urine specimens were collected. The primary renal outcome measure was reduction in estimated GFR. Renal events were defined as the need for renal replacement therapy (ESRD), an estimated halving of GFR, and/or a 25 ml/min per 1.73 m2 decline in GFR from baseline.

3 Archived Datasets

All data files, as provided by the Data Coordinating Center (DCC), are located in the CRIC study data package. For this replication, variables were taken from the derived datasets: “personlevel.sas7bdat”, “visitlevel.sas7bdat”, and “anc_vitd.sas7bdat”.

4 Statistical Methods

Analyses were performed to duplicate results for the data published by Reese et al. [1] in the American Journal of Nephrology, October 2013. To verify the integrity of the datasets, descriptive statistics were computed.
5 Results

For Table 1 in the publication [1], Table 1- Participant characteristics, overall and according to eGFR category, Table A lists the variables that were used in the replication and Table B compares the results calculated from the archived data file to the results published in Table 1.

There was a discrepancy found in the education and income variables listed in Table B below for the overall group.

6 Conclusions

There were some discrepancies compared to published results. The DCC confirmed the formats for INCOME and EDUCATION were listed in reverse order and that an erratum was sent to the journal.
